Metrics Evaluated for ALL 4 SUBGRAPHS (probably don't do this)

5) Community Detection

Because the community detection algorithms want an undirected graph and our current graph is directed, we need to convert it into an undirected graph first. Then, we can run all of the community detection algorithms on each subgraph and store it all inside one dataframe. We will also store the results inside a comunity objects data structure so that we can use the results later.

```
##    Subgraph   Algorithm N_communities Modularity_Q Max_Comm_Size
## 1         1 Fast Greedy             8       0.7267            56
## 2         1     Louvain             8       0.7462            51
## 3         1    Walktrap            10       0.7346            66
## 4         2 Fast Greedy             8       0.7086            44
## 5         2     Louvain             9       0.7090            47
## 6         2    Walktrap            20       0.6767            39
## 7         3 Fast Greedy             8       0.7685            45
## 8         3     Louvain            10       0.7886            35
## 9         3    Walktrap            10       0.7818            38
## 10        4 Fast Greedy             7       0.7436            40
## 11        4     Louvain             8       0.7396            38
## 12        4    Walktrap            12       0.7357            38
```

Looking at the results, we see that Walktrap generally detects more communities than the other 2 algorithms.

All of the algorithms have high modularity greater than 0.7, suggesting that they found clear communities.

6) Adjacency Matrix

Subgraph 1 − Original Node Order

Subgraph 2 − Original Node Order

Subgraph 3 − Original Node Order

Subgraph 4 − Original Node Order

Subgraph 1 − Reordered by Community

Subgraph 2 − Reordered by Community

Subgraph 3 − Reordered by Community

The adjacency matrix of each 200-node subgraph was examined to identify structural patterns in the Google web graph. Each entry in the matrix represents the presence of a directed hyperlink between two pages. In the original node ordering, edges appear scattered with no discernible pattern, reflecting the arbitrary order in which nodes were sampled. To reveal underlying structure, nodes were reordered by Louvain community membership. After reordering, clear diagonal block patterns emerged, particularly in Subgraph 4 which contained 1,608 edges. Each block along the diagonal represents a group of web pages that densely hyperlink to one another, likely corresponding to topically related pages. The sparsity off the diagonal indicates that pages from different communities rarely link directly to each other. This visual confirmation aligns with the community detection results, supporting the presence of meaningful cluster structure within the Google web graph.

7) Reordering Nodes for Community Detection

As we see above, all of the nodes are in one connected component. As such, this step is essentially the same as above. We will reorder the adjacency matrices for all of the remaining subgraphs as well.

Sub 1 : fast_greedy
Sub 1 : louvain
Sub 1 : walktrap
Node (reordered)
Node (reordered)
Node (reordered)
Node (reordered)
Node (reordered)
Node (reordered)

Sub 2 : fast_greedy
Sub 2 : louvain
Sub 2 : walktrap
Node (reordered)
Node (reordered)
Node (reordered)
Node (reordered)
Node (reordered)
Node (reordered)

Sub 3 : fast_greedy
Sub 3 : louvain
Sub 3 : walktrap
Node (reordered)
Node (reordered)
Node (reordered)
Node (reordered)
Node (reordered)
Node (reordered)

After reordering by community for each algorithm, we can see that the nodes form multiple boxes. This represents communities where nodes are highly interconnected. The adjacency matrix also happens to be mirrored across the y=x line, and that's because we used the undirected graph. We chose to use the undirected graph instead of the directed graph because that is the graph the algorithms used to detect the communities. If you also compare the adjencency matrix to the algorithm results, you see that the boxes correspond to how many communities each algorithm detected.

There are two main shapes we see in the adjacency matrix. First is this sparse L shape. This represents a central node that connects to many other nodes. In the context of Google, this could be a site like Wikipedia that has links to many different communities. Next is a solid box. This represents a community where all the nodes are closely interconnected. This could be a set of subpages, where all pages link to each other.
